Question 2

list of all the software classes/ conceptual class diagram:

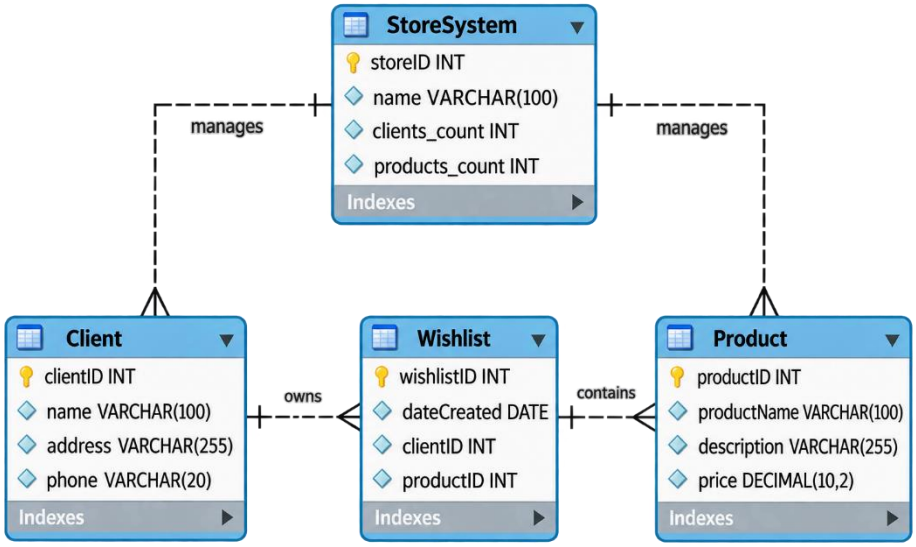

Explanation of why each software class is needed:

The client, product, and wishlist are the three software classes of the system. A consumer who utilizes the system is represented by a client. Every client must be added and identified by the system. An item that can be added to the system is represented by a product. Clients may then choose these items and add them to their wishlists. Products that a customer wishes to save for later are represented by a wishlist. Every customer may keep track of the things they are interested in by creating a wishlist. Together, these three software classes make it more simple for the system to handle the customers and the other requirements.

Explanation of whether any conceptual classes are dropped:

There aren't any conceptual classes that are dropped. The software system relies on all three components of the conceptual class client, Product, and Wishlist. The customer class stores information about each customer, and the Product class stores information about products. The Wishlist class tracks a client's wanted items. A new StoreSystem class is built to manage customers and activities. Actions like adding a client, adding a product, and adding a product to a wishlist are not considered distinct classes since they are better represented as methods within software classes.
